

# Quantum Chemistry on Quantum Computer

Guoqing Zhou, Yuzi He

# Quantum Computing

Qubit: superposition state

$$\alpha|0\rangle + \beta|1\rangle$$

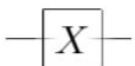

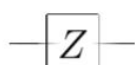

Quantum logical gate: Unitary Operator:

$$U^* U = \mathbf{1}$$

Physical Systems: ionic, photonic, superconducting and solid state systems.

# Some Quantum Logical Gates

1 qubit:

Hadamard		$\frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$
Pauli-X		$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$
Pauli-Y		$\begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix}$
Pauli-Z		$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$
Phase		$\begin{bmatrix} 1 & 0 \\ 0 & i \end{bmatrix}$
$\pi/8$		$\begin{bmatrix} 1 & 0 \\ 0 & e^{i\pi/4} \end{bmatrix}$

2 qubits

controlled-NOT

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$$

# Decompose the time evolution operator $\hat{U}$

Time evolution operator:

$$\hat{U}(t) = \exp(-i\hat{H}t)$$

1. Second-quantization
2. Transformation of the fermionic operators to spin variables
3. Exponentiation of the Hamiltonian
4. Circuit representations of the unitary propagator

# 1. Second quantization

## Hartree-Fock Method

$$\hat{H} = \sum_{p,q} h_{pq} \hat{a}_p^\dagger \hat{a}_p + \frac{1}{2} \sum_{p,q,r,s} h_{pqrs} \hat{a}_p^\dagger \hat{a}_q^\dagger \hat{a}_r \hat{a}_s$$

$$h_{pq} = \int dx \chi_p^*(x) \left( -\frac{1}{2} \nabla^2 - \sum_{\alpha} \frac{Z_{\alpha}}{r_{\alpha x}} \right) \chi_q(x)$$

$$h_{pqrs} = \int dx_1 dx_2 \frac{\chi_p^*(x_1) \chi_q^*(x_2) \chi_r(x_2) \chi_s(x_1)}{r_{12}}$$

$\chi_q(x)$  : single-particle basis

Mapping from state space to qubits

$|0\rangle$  : occupied,  $|1\rangle$  : unoccupied

Required N qubits for a system with N spin-orbitals

## 2. Transformation of the fermionic operators to spin variables: Third Quantization

**Jordon-Wigner Method:**

$$\hat{a}_j \rightarrow \mathbf{1}^{\otimes j-1} \otimes \hat{\sigma}^+ \otimes (\hat{\sigma}^z)^{\otimes N-j}$$

$$\hat{a}_j^+ \rightarrow \mathbf{1}^{\otimes j-1} \otimes \hat{\sigma}^- \otimes (\hat{\sigma}^z)^{\otimes N-j}$$

$$\hat{\sigma}^z = |0\rangle\langle 0| + |1\rangle\langle 1|$$

$$\hat{\sigma}^+ = |0\rangle\langle 1|$$

$$\hat{\sigma}^- = |1\rangle\langle 0|$$

**Other Methods: Bravyi-Kitaev, Bravyi-Kitaev super fast**

### 3: Exponentiation of hamiltonian

Trotter-Suzuki decomposition:

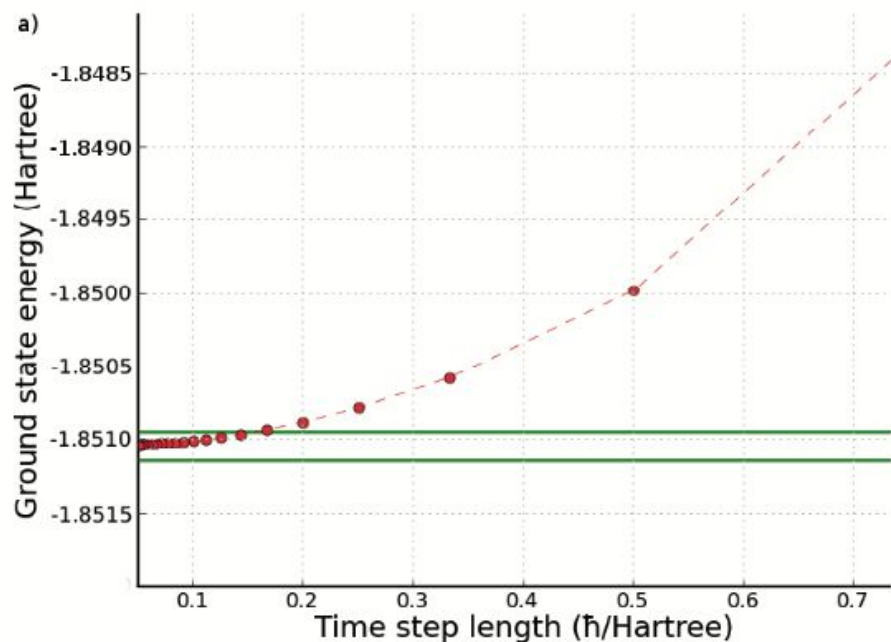

$$\hat{\mathbf{H}} = \sum_{i=1}^N \hat{h}_i$$

$$\hat{U}(t) = e^{-i\hat{H}t} = (e^{-i\hat{h}_1 dt} e^{-i\hat{h}_2 dt} \dots e^{-i\hat{h}_N dt})^{\frac{t}{dt}} + O(dt^2)$$

Approximation becomes exact as:

$$T_n = t/dt \rightarrow \infty$$

### 3: Exponentiation of hamiltonian

Error with respect to the time step, and number of quantum logical gates required with given time step for the calculation of Hydrogen molecules

# 4: Circuit representation of the unitary propagator

Unitary operator:  $\hat{U}(dt)$

Controlled Unitary:  $c - \hat{U}(dt)$

Control qubit is 1, then propagate

$$|1, \psi \rangle \rightarrow \hat{U}|1, \psi \rangle$$

If it is 0, don't propagate

Require  $O(N^5)$  quantum logical gates without considering error correction.

Second quantized operators	Circuit
Number operator $h_{pp} a_p^\dagger a_p$	
Excitation operator $h_{pq}(a_p^\dagger a_q + a_q^\dagger a_p)$	
Coulomb and exchange operators $h_{pqpp} a_p^\dagger a_q^\dagger a_q a_p$	
Number-excitation <sup>a</sup> operator $h_{pqqr} (a_p^\dagger a_q^\dagger a_q a_r + a_r^\dagger a_q^\dagger a_q a_p)$	
Double excitation operator $h_{pqrs} (a_p^\dagger a_q^\dagger a_r a_s + a_s^\dagger a_r^\dagger a_q a_p)$	

# Calculation of Hydrogen molecule

Basis: STO-3G,  $|1s\rangle$ , with spin, there are 6 spin-orbitals

Due to the symmetries, Hamiltonian is block-diagonal, with dimensions 1, 1, 2, 2

The problem is reduced to estimate the eigenvalues of 2 by 2 matrices.

The iterative phase estimation algorithm (IPEA) is used to evaluate the energy.

Eigenstates preparation:

for hydrogen molecules, known from symmetry requirement.

Generally, one can use adiabatic state preparation technique

# Quantum Phase Estimation

In this section, I will explain the the method used to estimate quantum phase in detail.

Suppose we have obtained a eigenstate of a given hamiltonian  $H$

Under the time translation operator, the eigenstate will behave as  $U = \exp(-iHt/\hbar)$ ,

$$U |\psi\rangle = e^{-iEt/\hbar} |\psi\rangle = e^{i2\pi\phi} |\psi\rangle$$

This indicates that by measuring phase angle and the time interval which the operator  $U$  is applied, we are able get the eigen energy  $E$ .

# Naive Version of Iterative Phase Estimation Algorithm (IPEA)

Consider the following quantum circuit:

Right before measuring, the state is  $\frac{1}{2}[(1 + e^{i2\pi\phi})|0\rangle + (1 - e^{i2\pi\phi})|1\rangle]|\Psi\rangle$

Which implies the probability of getting state 0 is  $P_0 = \cos^2(\pi\phi)$

Assume  $N$  experiment, the accuracy of  $P_0$  is  $1/\sqrt{N}$ . For  $m$  digits of phase angle,

We need  $2^{(2m)}$  measurements.

# Kitaev's Improved IPEA

Assume we can apply  $U$  multiple times.  $R_z$  is can adjust the phase between 0, 1.

By definition phase angle satisfies  $0 \leq \phi < 2\pi$

We expand it into binary digits, ex.  $0.f_1f_2f_3f_5\dots$ ,  $f_i = 0, 1$

If we do the measurement now, the probability of getting 0 is given by

$$P_0 = \cos^2(\pi(2^{k-1} - \omega_k))$$

## Kitaev's Improved IPEA (Cont.)

We plug in the binary form of the phase angle,

$$2^{k-1} \phi - \omega_k = (f_1 f_2 \dots f_{k-1} . f_k f_{k+1} \dots) - \omega_k$$

Let  $\omega_k = (0.0 f_{k+1} f_{k+1})$

$$P_0 = \cos^2(\pi(2^{k-1} \phi - \omega_k)) = \cos^2(\pi(0.f_k))$$

This probability is deterministic.

Method: Start from the last digit of the phase, repeat measurements.

Put the previous results into phase adjuster Rz. Repeat till the first digits is recovered.

# Kitaev's Improved IPEA Accuracy

In real life, the binary expansion of phase angle is not exact.

The remainder is  $\delta 2^{-m}$ ,  $0 \leq \delta < 1$

Assuming all previous measurements are correct, the probability of current measurement to be correct is

$$P_k = \cos^2(\pi 2^{k-m-1} \delta)$$

The probability of correctly measuring all  $m$  digits are given by

$$P(\delta) = \prod_{k=1}^m P_k = \frac{\sin^2(\pi \delta)}{2^{2m} \sin^2(\pi 2^{-m} \delta)},$$

This probability is lower bounded by  $P(1/2) = 4/\pi^2$
